

Executive Summary:

Title:

Tick Tock Project Verified vs Unverified Accounts

Subtitle:

Data Exploration and Hypothesis Testing Results.

Project Overview:

In this phase of the classification project, descriptive and inferential statistics were applied to analyze user engagement. The main purpose was to determine if a statistically significant difference exists in the number of viewers for videos posted by verified and unverified accounts.

Key Insights:

- The two-sample t-test comparing average view counts for both verified and unverified accounts, which resulted in p-value significantly lower than the 0.05 threshold for both verified and unverified accounts.
- The null hypothesis, which states that there is no difference in viewer counts between the two groups, was rejected.
- There is a proven and statistically significant difference between videos posted by verified and unverified TikTok accounts.

Details:

Methodology: Exploratory data analysis (EDA) and a Two-Sample T-Test using Python.

Significance level: 5%(0.05).

Variable Tested: Verified-status (Categorical) and video_view_count(Continuous).

Next Steps:

Investigate the Root Causes: Further research and investigation need to be conducted to understand the underlying behavioral differences that cause such different view counts.

Monitor unverified Account Activities: Analyze unverified accounts to determine if a spam bot is artificially causing an inflation in the viewer count.

Feature Engineering: Incorporate verified_status as a key feature in the upcoming machine learning classification model.
